An active magnetic bearing (100) with autodetection of position, the bearing comprising at least first and second opposing electromagnets (120, 130) forming stators disposed on either side of a ferromagnetic body (110) forming a rotor and held without contact between said electromagnets. The first (120, 130) each comprising second electromagnets and magnetic circuit (121; 131) essentially constituted by a first material and co-operating with said ferromagnetic ferromagnetic body to define an airgap, together with an excitation coil (122; 132) powered from a power amplifier whose input current is servo-controlled as a function of the position of the ferromagnetic body relative to the magnetic circuits of the first and second electromagnets. of the ferromagnetic body (110) being measured from the inductance detected between the two electromagnets (120, 130) in response to simultaneous injection into both opposing electromagnets of a sinusoidal current at a frequency that is greater than the closed loop passband of the system. magnetic circuit (121; 131) of each electromagnet further includes a portion (124; 134) in the vicinity excitation coil (122; 132) that uses a second ferromagnetic material having magnetic permeability that is lower than that first material and electrical resistivity that is higher than that of the first material so as to encourage the the high frequency magnetic fields passage of that are generated in the bearing.
